$|0.05M - 4000| = e^{\frac{t}{20} + \frac{C}{20}}$

$0.05M - 4000 = Ae^{\frac{t}{20}}$ where $A = \pm e^{\frac{C}{20}}$

$M = 80000 + 20Ae^{\frac{t}{20}}$

When $t = 0$, $M = K$

$K = 80000 + 20A$

$20A = K - 80000$

Hence $M = 80000 + (K - 80000)e^{\frac{t}{20}}$

8 (ii)	$z=\sqrt{3}+i \quad (\because k>0)$ $\|z\|=\sqrt{1+3}=2$ $\arg(z)=\frac{\pi}{6}$  	

	<u>Method 1: By Polar Form & Trigonometry</u> $z = 2e^{i\pi/6} = 2\left(\cos\frac{\pi}{6} + i\sin\frac{\pi}{6}\right)$ $z^n = 2^n e^{in\pi/6} = 2^n\left(\cos\frac{n\pi}{6} + i\sin\frac{n\pi}{6}\right)$ z^n is real $\Leftrightarrow \sin\frac{n\pi}{6} = 0$ $\Leftrightarrow \frac{n\pi}{6} = k\pi,$ where $k \in \mathbb{Z}$ $\Leftrightarrow n = 6k,$ where $k \in \mathbb{Z}$ Hence, $n = 0, \pm 6, \pm 12, \pm 18, \ldots$ **<u>Method 2: By Properties of arg(z)</u>** $\arg(z^n) = n\arg(z) = \frac{n\pi}{6}$ z^n is real, the point representing z^n on the Argand diagram is on the x-axis. Thus, $\arg(z^n) = \frac{n\pi}{6} = k\pi,$ where $k \in \mathbb{Z}$ $\therefore n = 6k,$ where $k \in \mathbb{Z}$ i.e. $n = 0, \pm 6, \pm 12, \pm 18, \ldots$ Given $\left\|z^n\right\| > 100$. $\left\|z^n\right\| = \left\|z\right\|^n = 2^n$ Hence, $2^n > 100$ But n is a multiple of 6. We then have $2^6 = 64 < 100$ $2^{12} = 4096 > 100$ The least value of n is then 12.	
9	Let P_n be the statement $\sum_{r=1}^{n}\frac{3r+1}{r(r+1)(r+2)} = \frac{n(7n+9)}{4(n+1)(n+2)}$ for all integers $n \geq 1$. When n = 1, LHS = $\sum_{r=1}^{1}\frac{3r+1}{r(r+1)(r+2)} = \frac{3+1}{1(2)(3)} = \frac{2}{3}$ RHS = $\frac{7+9}{4(2)(3)} = \frac{2}{3}$ = LHS $\therefore \mathrm{P}_1$ is true. Assume that P_k is true for **some** positive integer k, $k \geq 1$, i.e. $\sum_{r=1}^{k}\frac{3r+1}{r(r+1)(r+2)} = \frac{k(7k+9)}{4(k+1)(k+2)}$ Need to prove P_{k+1} is true,	

i.e. $\sum_{r=1}^{k+1} \frac{3r+1}{r(r+1)(r+2)} = \frac{(k+1)(7k+16)}{4(k+2)(k+3)}$.

LHS of $P_{k+1} = \sum_{r=1}^{k+1} \frac{3r+1}{r(r+1)(r+2)}$

$$= \sum_{r=1}^{k} \frac{3r+1}{r(r+1)(r+2)} + \frac{3(k+1)+1}{(k+1)(k+2)(k+3)}$$

$$= \frac{k(7k+9)}{4(k+1)(k+2)} + \frac{3k+4}{(k+1)(k+2)(k+3)}$$

$$= \frac{7k^3+30k^2+39k+16}{4(k+1)(k+2)(k+3)}$$

$$= \frac{(7k^2+23k+16)(k+1)}{4(k+1)(k+2)(k+3)}$$

$$= \frac{(k+1)(7k+16)}{4(k+2)(k+3)} = \text{RHS}$$

$\therefore$ P_k is true $\Rightarrow$ P_{k+1} is true.

Since P_1 is true, and P_k is true $\Rightarrow$ P_{k+1} is true, by the Principle of Mathematical Induction, $\sum_{r=1}^{n} \frac{3r+1}{r(r+1)(r+2)} = \frac{n(7n+9)}{4(n+1)(n+2)}$ is true for all integers $n \geq 1$.

9 (i)

$$\frac{n(7n+9)}{4(n+1)(n+2)} = \frac{7}{4} - \frac{6n+7}{2(n+1)(n+2)}$$

Since n is a positive integer, $\frac{6n+7}{2(n+1)(n+2)} > 0$

$$\therefore \sum_{r=1}^{n} \frac{3r+1}{r(r+1)(r+2)} = \frac{n(7n+9)}{4(n+1)(n+2)} = \frac{7}{4} - \frac{6n+7}{2(n+1)(n+2)} < \frac{7}{4}$$

Alternatively,

$$\sum_{r=1}^{n} \frac{3r+1}{r(r+1)(r+2)} = \sum_{r=1}^{n} \frac{1}{2r} + \frac{2}{r+1} - \frac{5}{2(r+2)} = ... = \frac{7}{4} - \frac{1}{2(n+1)} - \frac{5}{2(r+2)} < \frac{7}{4}$$

Since n is a positive integer, $-\frac{-1}{2(n+1)} - \frac{5}{2(n+2)} < 0$

9 (ii)	$(r+1)^3 = r^3 + 3r^2 + 3r + 1$ $r(r+1)(r+2) = r^3 + 3r^2 + 2r$ $\therefore (r+1)^3 > r(r+1)(r+2)$ $\sum_{r=1}^{n} \frac{3r}{(r+1)^3} < \sum_{r=1}^{n} \frac{3r}{r(r+1)(r+2)} < \sum_{r=1}^{n} \frac{3r+1}{r(r+1)(r+2)} < \frac{7}{4}.$	
10	$y = \frac{x^2 - 4k^2}{x-k}$ where k is a constant such that $k \neq 0$ $xy - ky = x^2 - 4k^2$ $x^2 - xy + (ky - 4k^2) = 0$ x is real $\Rightarrow$ discriminant ≥ 0 $y^2 - 4\left(ky - 4k^2\right) \geq 0$ $y^2 - 4ky + 16k^2 \geq 0$ $\left(y - 2k\right)^2 + 12k^2 \geq 0$ This inequality is true for all values of y. Therefore y can take the set of all real numbers. *Alternative Method:* $\frac{dy}{dx} = 0$ $\frac{x^2 - 2xk + 4k^2}{\left(x-k\right)^2} = 0$ $x^2 - 2xk + 4k^2 = 0$ discriminant = $-12k^2 < 0$ no real roots. The locus $\lvert z - z_2 \rvert = \lvert z - z_3 \rvert$ is a perpendicular bisector of the line segment P_2P_3 where $P_2 \equiv z_2$ and $P_3 \equiv z_3$. Since OP_2P_3 is an isosceles triangle, the perpendicular cuts through the origin and bisect the angle P_2OP_3. Thus the perpendicular bisector is inclined at angle $\frac{\pi}{10}$ radian below the positive *x*-axis. Hence, the Cartesian equation of the locus $\lvert z - z_2 \rvert = \lvert z - z_3 \rvert$ is $y = -x\tan(\frac{\pi}{10})$ OR $y = x\tan(\frac{9\pi}{10})$ $\arg(z - z_1) = \arg(z_4)$
